Methods

Data origins and preprocessing

We generated a mixuture dataset combining three different recent breast cancer studies. The first

one is a breast cancer dataset consisting of 100k cells from a single-cell atlas of human breast cancers

\$Wu et al. [2021]. The second dataset consisted of 48k cells from a single-cell atlas of the healthy

breast tissues (Bhat-Nakshatri et al. [2021]). The third dataset is 6k subset of breast cancer CD4

and CD8 T-cells from a pan-cancer atlas of tumour-infiltrating T cells profiled across 21 cancer

types and 316 donors (Zheng et al. [2021]). The total number of cells in the combined dataset was

155913. We filtered out genes detected in less than 3 cells along with mitochondrial gene and spike

genes, which lead to 20265 genes in the final dataset.

The SPRUCE Model

The SPRUCE model consists of two steps of topic modeling - first, we model cell topic to assign

each cell into type/state, and then we use these cell topics to construct a set of neighbours and

model interaction topic, which assigns each neighbour pair to unique interaction state.

Cell topic analysis

The cell topic modeling extends on the ideas of LDA. Consider a sample of cells  $i_1, ...., i_N$  and a

list of genes  $g_1, ..., g_G$ , where  $x_{i1}, x_{i2}, ..., x_{iG}$  are raw count data for G genes in cell i. We assume

1

that each cell count vector  $X_i$  was generated from a multinomial distribution parameterized by a gene expression frequency matrix with an element  $\rho_{ig}$  of a gene g in the cell i.

$$p(\mathbf{x}_i|\rho_i) = \prod_g \rho_{ig}^{X_{ig}}$$

We introduce Dirichlet prior on the  $\rho$  and parameterize the Dirichlet as a generalized linear model (GLM). Exploiting the conjugacy between the multinomial and Dirichlet, we integrate out the unknown parameters  $\rho$ .

$$p(\rho_i|\lambda_i) = \frac{\Gamma(\sum_g \lambda_{ig})}{\prod_g \Gamma(\lambda_{ig})} \prod_{g \in \mathsf{genes}} \rho_{ig}^{\lambda_{ig}-1}$$

$$\lambda_{ig} = \exp\left(\sum_{t=1}^{T} \theta_{it} (\beta_{tg} + b_g)\right)$$

The topic proportion  $\theta_{it}$  for cell i is drawn from logistic normal distribution with model hyperparameters  $\delta_{it}$  and we assume topic proportions within a simplex, namely  $\sum_{t \in \text{topics}} \theta_{it} = 1$ .

$$\delta_{it} \sim LN(0, I); \theta_{it} = softmax(\delta_{it}) \tag{1}$$

The marginal likelihood

$$p(\mathbf{x}_i|\cdot) = \frac{\Gamma(\sum_g \lambda_{ig})}{\sum_g \Gamma(\lambda_{ig})} \frac{\Gamma(\sum_g \lambda_{ig} + X_{ig})}{\sum_g \Gamma(\lambda_{ig} + X_{ig})}$$

The marginal likelihood of each cell is an intractable problem because it involves integral over the topic proportion. Variational inference techniques can be used to approximate this type of intractable integrals.

Let  $p_{\theta}(z \mid x)$  be a true posterior and  $q_{\phi}(z \mid x)$  be an approximate posterior.

$$\begin{split} D_{KL}(q_{\phi} \mid\mid p_{\theta}) &= E_{q_{\phi}}[\log \frac{q_{\phi}(z \mid x)}{p_{\theta}(z \mid x)}] \\ &= E_{q_{\phi}}[\log q_{\phi}(z \mid x)] - E_{q_{\phi}}[\log p_{\theta}(z \mid x)] \\ &= E_{q_{\phi}}[\log q_{\phi}(z \mid x)] - E_{q_{\phi}}[\log \frac{p_{\theta}(z, x)}{p_{\theta}(x)}] \\ &= E_{q_{\phi}}[\log q_{\phi}(z \mid x)] - E_{q_{\phi}}[\log p_{\theta}(z, x)] + E_{q_{\phi}}[\log p_{\theta}(x)] \\ &= E_{q_{\phi}}[\log q_{\phi}(z \mid x)] - E_{q_{\phi}}[\log p_{\theta}(z, x)] + \int q_{\phi}(z \mid x)\log p_{\theta}(x)dz \\ &= E_{q_{\phi}}[\log q_{\phi}(z \mid x)] - E_{q_{\phi}}[\log p_{\theta}(z, x)] + \log p_{\theta}(x) \int q_{\phi}(z \mid x)dz \\ &= E_{q_{\phi}}[\log q_{\phi}(z \mid x)] - E_{q_{\phi}}[\log p_{\theta}(z, x)] + \log p_{\theta}(x) \\ &\log p_{\theta}(x) = -E_{q_{\phi}}[\log q_{\phi}(z \mid x)] + E_{q_{\phi}}[\log p_{\theta}(z, x)] + D_{KL}(q_{\phi} \mid\mid p_{\theta}) \end{split}$$

Here,  $D_{KL}(q_{\phi} \mid\mid p_{\theta})$  is intractable but it is always  $\geq 0$ , we can use this property to remove  $D_{KL}$  from the equation and the marginal log likelihood  $\log p_{\theta}(x)$  will be at least  $\geq -E_{q_{\phi}}[\log q_{\phi}(z\mid x)] + E_{q_{\phi}}[\log p_{\theta}(z,x)]$ . Since this term is the lower bound on the evidence, it is called as Evidence Lower Bound(ELBO). We maximize the marginal log likelihood by maximizing the ELBO and indirectly minimize the KL divergence.

$$\begin{split} ELBO &= -E_{q_{\phi}}[\log\,q_{\phi}(z\mid x)] + E_{q_{\phi}}[\log\,p_{\theta}(z,x)] \\ &= -E_{q_{\phi}}[\log\,q_{\phi}(z\mid x)] + E_{q_{\phi}}[\log\,p_{\theta}(x\mid z)] + E_{q_{\phi}}[\log\,p_{\theta}(z)] \\ &= E_{q_{\phi}}[\log\,p_{\theta}(x\mid z)] - E_{q_{\phi}}[\log\,q_{\phi}(z\mid x)] + E_{q_{\phi}}[\log\,p_{\theta}(z)] \\ ELBO &= E_{q_{\phi}}[\log\,p_{\theta}(x\mid z)] - E_{q_{\phi}}[\log\frac{q_{\phi}(z\mid x)}{p_{\theta}(z)}] \end{split} \tag{3}$$

Here,  $E_{q_{\phi}}[\log p_{\theta}(x \mid z)]$  is an expected reconstruction error and  $E_{q_{\phi}}[\log \frac{q_{\phi}(z|x)}{p_{\theta}(z)}]$  is KL Divergence between approximate posterior and the prior.

Approximate posterior and prior

The approximate posterior  $q_{\phi}(z \mid x)$  is a Gaussian variational distribution  $q(\delta_i; i_n, v) = N(\mu, \Sigma)$ 

whose mean and variance are constructed form a neural network parameterized by v. The network takes raw count data of a cell  $i_n$  for G genes and outputs a mean and variance of  $\delta_i$ . The prior  $p_{\theta}(z) = N(0, I)$ . The KL divergence between these two form of Gaussians exist in closed form and given as-

$$\begin{split} D_{KL}(q_{\phi} \mid\mid p_{\theta}) &= E_{q_{\phi}}[log\frac{q_{\phi}(z\mid x)}{p_{\theta}(z)}] \\ &= E_{q_{\phi}}[log\;q_{\phi}(z\mid x)] - E_{q_{\phi}}[log\;p_{\theta}(z)] \\ &= 1/2\sum_{d}(1 + log(\Sigma) - \mu^2 - \Sigma) \end{split} \tag{4}$$

In addition to the latent state KL divergence, we take into account the uncertainty of  $\beta_{tg}$  parameters:

$$\beta_{ta} \sim \mathcal{N}(0,1)$$

Total Expected log-likelihood Lower-bound (ELBO):

$$\frac{J}{n} = \frac{1}{n} \sum_{i=1}^{n} \log p(\mathbf{x}_i | \theta_i(\mathbf{z}_i), \beta)$$
 (5)

$$+ \frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} D_{\mathsf{KL}} \left( q(z_{it}) \| p(z_{it}) \right) \tag{6}$$

$$+ \frac{1}{n} \sum_{t=1}^{T} \sum_{g=1}^{G} D_{\mathsf{KL}} \left( q(\beta_{tg}) \| p(\beta_{tg}) \right) \tag{7}$$

(8)

#### Neighbour cells calculation

A set of neighbour cells were calculated for each cell using the topic assignment from cell topic model. For each cell, five neighbours from each topic were calculated using ANNOY. In total, we generated 159 neighbours for each cell - 32 topics and 5 neighbours from each topic. - removed self neighbour pair. 18 topics with cell count less than 100 were removed during generating annoy model list. Topics were not removed during generating neighbours, only selected topics were used to create a model list.

#### Ligan receptor data augmentation

For each cell pair, we selected ligand and receptors genes from celltalkDB database and incorporated known interactions from the database using the transformation of spaces as shown in the figure.

### Interaction topic analysis

Multinomial-Dirichlet:

$$p(\mathbf{y}_i|\mathbf{q}_i) = \frac{(\sum_g Y_{ig})!}{\prod_g Y_{ig}!} \prod_g q_{ig}^{Y_{ig}}$$

$$\mathbf{q}_i \sim \mathrm{Dir}(\mathbf{q}_i|\rho_i) = \frac{\Gamma(\sum_g \rho_{ig})}{\prod_g \Gamma(\rho_{ig})} \prod_g q_{ig}^{\rho_{ig}-1}$$

Single-cell generative model:

$$p(\mathbf{x}_j|\cdot) = \frac{\Gamma(\sum_g \lambda_{jg})}{\sum_g \Gamma(\lambda_{jg})} \frac{\Gamma(\sum_g \lambda_{jg} + X_{jg})}{\sum_g \Gamma(\lambda_{jg} + X_{jg})}$$

where

$$\lambda_{jg} = \lambda_0 \exp \left( \sum_{t=1}^T \theta_{jt} (\beta_{tg} + \delta_g) \right)$$

$$\lambda_0 = \exp(\tilde{\lambda}_0)$$

$$\sum_{t} \theta_{jt} = 1$$

Bayesian regularization of the model parameters

$$\beta_{tq} \sim \mathcal{N}(0, 1)$$

Total Expected log-likelihood Lower-bound (ELBO):

$$\frac{J}{n} = \frac{1}{n} \sum_{i=1}^{n} \log p(\mathbf{x}_i | \theta_i(\mathbf{z}_i), \beta)$$
(9)

$$+ \frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} D_{\mathsf{KL}} \left( q(z_{it}) \| p(z_{it}) \right) \tag{10} \label{eq:10}$$

$$+ \frac{1}{n} \sum_{t=1}^{T} \sum_{l=1}^{L} D_{\mathsf{KL}} \left( q(\beta_{tl}) \| p(\beta_{tl}) \right) \tag{11}$$

$$+ \frac{1}{n} \sum_{t=1}^{T} \sum_{r=1}^{R} D_{\mathsf{KL}} \left( q(\beta_{tr}) \| p(\beta_{tr}) \right) \tag{12}$$

## Results

Probabilistic topic models identify resident cell types and cancer subtypes

Cell-cell interaction topics reveal new cancer types

Different interaction topics induce subtype-specific gene-gene networks

Each interaction topic show disjoint differential expression genes
